

## Benthic marine flora of Kornati National Park (Kornati Archipelago, Middle Adriatic, Croatia)

Ante ŠPAN and Boris ANTOLIĆ

*Institute of Oceanography and Fisheries, Split, Croatia*

A check list of the marine benthic flora of Kornati National Park (Kornati Archipelago, Middle Adriatic) was compiled on the basis of long-term personal collections and sparse bibliographical data. The list includes 352 specific and infraspecific taxa of algae (225 Rhodophyta, 75 Phaeophyta, 52 Chlorophyta) and 3 species of seagrasses, of which 255 are reported from the archipelago for the first time. The R/P ratio of 3 indicates a subtropical flora. The flora is analyzed in terms of its phytogeographical components.

### INTRODUCTION

The benthic marine algae and seagrasses of the Kornati Archipelago have been studied sporadically and therefore have remained almost unknown. VOUK (1930) collected algae along parts of the coast of some islets (Obručan Mali, Obručan Veli and Borovnik) and of the island Kornat during his biological research of the mid-Dalmatian islands in May 1925. He collected from deeper bottoms, between the islets Gustac and Klobučar, and along the coast of Lavernaka by dredge.

Since the samplings were sporadic, as stated by VOUK himself, only 47 specific and infraspecific taxa were collected (13 Chlorophyceae, 9 Phaeophyceae and 25 Rhodophyceae). Reports of some algal species from the Kornati Archipelago may be found but rarely in papers by ERCEGOVIĆ (1949, 1952, 1955 a, 1955 b, 1956, 1963). ANTOLIĆ (1985) identified 59 epiphytic algae on the leaves of *Posidonia oceanica* from the Kornati Archipelago during spring and summer. No

complete floristic study of the archipelago has been made previous to the present investigation.

In 1979, we started a program of sampling the benthic algae and seagrasses of the rocky shores of Kornat Island, the cliffs of smaller outer islands and the bottoms around them as part of a study of the marine flora and fauna of Kornati National Park. The vertical and horizontal distribution of the benthic flora was preliminarily described by ŠPAN and ANTOLIĆ (1990). A check list of all benthic marine algae and seagrasses known from the park is presented here.

### MATERIAL AND METHODS

This investigation was carried out between 1979 and 1989. The benthic flora was sampled mainly by SCUBA diving at shallow depths and by dredging at greater depths (50.-100 m).

Algal material was collected from a large number of stations along the transects from the supralittoral to the circalittoral zone (distinc-

tion made by PÉRÈS and PICARD, 1958). A number of transects were located along the coasts of outer islands and reefs (Purara, Volić, Ravní Žakan, Kameni Žakan, Lunga, Lavsa, Panitula Mala, Piškera, Rašip Veli, Rašip Mali, Mana, Plešćina, Obručan Veli, Obručan Mali) and the coves Prisliga, Stinjiva, Zala Draga and Vrulja on Kornat Island and in Lojena cove on Lavernaka Island. Collections were carried out also at submarine cliffs, submarine sills, reefs and deeper mobile bottoms and well developed coralligenous bottoms near the above mentioned outer islands (Fig. 1). In compiling the inventory of benthic flora, sparse bibliographical were used too.

For categorization and identification of higher taxonomic categories (classes and orders) the classification by PARKE and DIXON (1976), BOUDOURESQUE *et al.* (1984), BOUDOURESQUE and PERRET-BOUDOURESQUE (1987), Hoek *et al.* (1988), PERRET-BOUDOURESQUE and SERIDI (1989) and RIBERA *et al.* (1992) was used. For determination of collected algal material the following references

was consulted: HAUCK (1885), ERCEGOVIĆ (1948, 1949, 1952, 1955 a, 1955 b, 1956, 1957, 1963), FELDMANN (1942), FELDMANN-MAZOYER (1940), FUNK (1927, 1955), HAMEL (1931-1939), HAMEL and LEMOINE (1952), KYLIN (1956), BLIDING (1960, 1963, 1968), HOEK (1963), GIACCOME (1972-1973, 1978), GIACCOME and BRUNI (1973), GIACCOME and BRYCE-DERNI (1972), BRESSAN (1974), CODOMIER (1971), BOUDOURESQUE and DENIZOT (1975), KORNmann and SAHLING (1977), COPPEJANS (1983), ZINNOVA (1967).

We modified slightly the schema proposed by GIACCOME *et al.* (1985) for delineating phytogeographic regions of benthic algae and seagrasses, as follows: M (Mediterranean), A (Atlantic including Ab - Atlantic-boreal, At - Atlantic-tropical and Abt - Atlantic-boreal-tropical taxa), C (cosmopolitan), SC (subcosmopolitan), AP (Atlantic-Pacific including APo - holo Atlantic-Pacific, APt - Atlantic-Pacific-tropical and APtc - Atlantic-Pacific-tropical-cold), IA (Indo-Atlantic including IAo - holo Indo-Atlantic, IAt - Indo-Atlantic-tropical and IAtc -

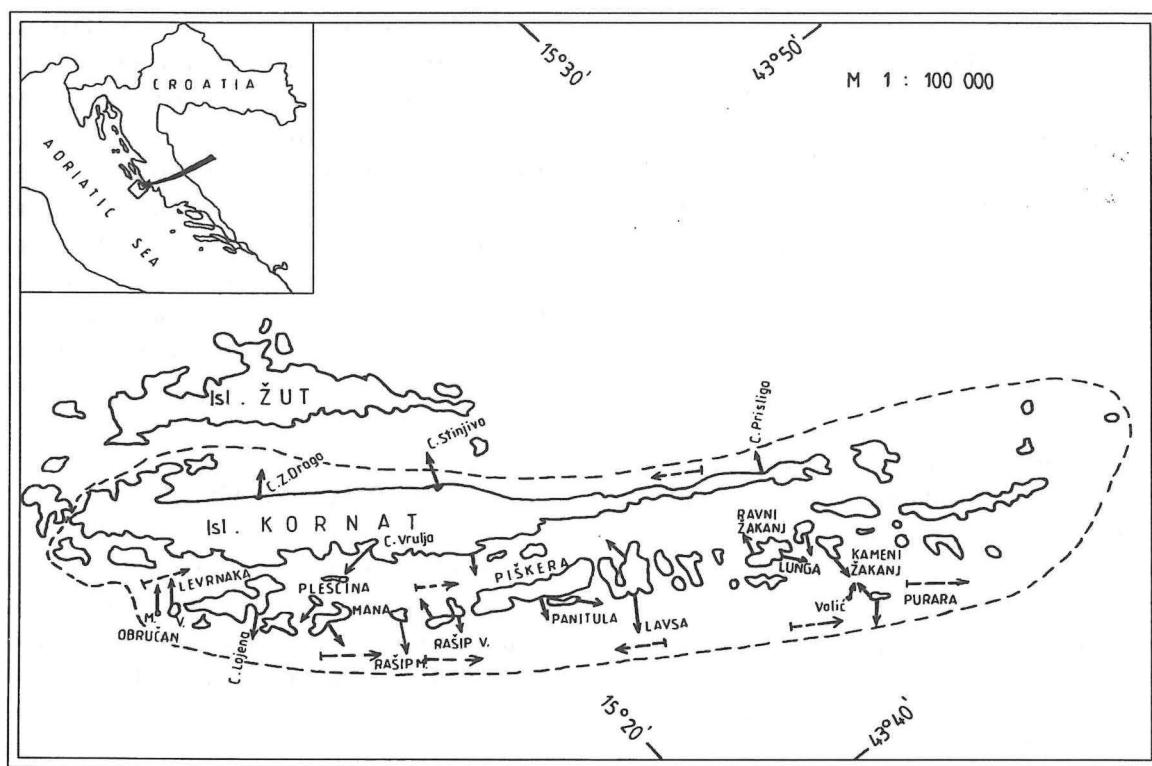

Fig. 1. Map of investigations in the Kornati National Park

----- border of Kornati National Park      → transects      → dredging

Indo-Atlantic-tropical-cold taxa), IP (Indo-Pacific), CB (circumboreal), CT (circumtropical) and EAD (endemic-Adriatic).

## RESULTS AND DISCUSSIONS

The benthic flora consists of 352 specific and infraspecific taxa of macroalgae and 3 species of seagrasses. Algae were separated in four classes: Bangiophyceae, Florideophyceae, Fucophyceae and Chlorophyceae with a total of 28 orders and 177 genera (see ANEX).

The benthic flora is dominated by representatives of the division Rhodophyta (Bangiophyceae and Florideophyceae) with a 186 species, 32 varieties, 5 forms and 2 stages or 63.9%. Phaeophyta (Fucophyceae) represented by a smaller number of taxa (55 species, 2 subspecies, 11 varieties, 5 forms and 2 stages) with a lower percentage (21.3%), while Chlorophyta (Chlorophyceae) are represented by 47 species, 2 varieties, 2 forms and 1 stage of 14.8%. This inventory is not complete since some genera, such as *Audouinella*, *Lithophyllum*, *Lithohamnion*, *Polysiphonia* (Rhodophyta), *Ectocarpus* (Phaeophyta) and *Cladophora* (Chlorophyta) have not yet been completely worked out. A comparison of the benthic flora of Kornati Archipelago with the flora of islands Vis and Biševo (ŠPAN, 1980) and islet Jabuka (ERCEGOVIĆ, 1957) in the open middle Adriatic showed that the flora of Kornati is poorer than that of Vis and Biševo, and slightly richer than that of the islet of Jabuka (Table 1). To be noted that while the number of Chlorophyta in the three floras is quite similar, some differences do exist in the number of Phaeophyta: greater between the flora of Kornati and that of Vis-Biševo, much lower between Kornati and Jabuka floras; on the contrary, a great difference in the number of Rhodophyta does exist between the flora of Kornati and that of Jabuka (considerably lower between Kornati and Vis-Biševo floras).

The comparison based on per cent values (Table 1), shows increasing values of Rhodophyta from Jabuka (55.2 %) to Vis-Biševo (58.8 %), with the highest in Kornati Islands

(63.9 %); increasing values of Phaeophyta from Kornati (21.3%) to Vis-Biševo (26.6 %), with the highest in Jabuka (28.7 %); while values of Chlorophyta are rather similar in the three areas, with a slightly higher values (16.4 %) in Jabuka.

Table 1. Numbers (N) and percentages (%) of Rhodophyta, Phaeophyta and Chlorophyta members and R/P ratios calculated for floras of Kornati, Vis-Biševo and Jabuka.

Area Division	Kornati		Vis-Biševo		Jabuka	
	N	%	N	%	N	%
RHODOPHYTA	225	63.9	237	58.8	148	55.0
PHAEOPHYTA	75	21.3	107	26.6	77	28.6
CHLOROPHYTA	52	14.8	59	14.6	44	16.4
T O T A L	352		403		269	
R/P	3.0		2.2		1.9	

The differences in the R/P ratio (Table 1) and in the chorological spectra (Table 2) point out different phytogeographic characters of three benthic floras. The R/P ratio (3.0) in the Kornati benthic flora is rather high, and in any case higher than those of Vis-Biševo (2.2) and Jabuka (1.9). The ratio obtained for benthic flora of Kornati Archipelago is that of a subtropical flora. On the contrary, low ratio values obtained for Vis-Biševo and particularly for Jabuka benthic flora, suggest almost boreal character.

Benthic flora of Kornati Islands, like that of the Adriatic Sea, is not unique, but composed of floristic elements from different phytogeographic regions (Table 2). The best represented floristic elements are the Atlantic (A) with 123 taxa or 34.6 %, followed by the Mediterranean (M) with 96 taxa or 27.0 % and the cosmopolitan (C) and sub-cosmopolitan (SC) with a total of 60 taxa or 16.9 %.

A comparison of chorological spectra of the three benthic floras was also made (Table 2). To be noted that the endemic-Adriatic element shows the lowest percentage value (3.4 %) in the Kornati area (9.9 % and 12.2 % in Vis-Biševo and Jabuka respectively). The Atlantic and Mediterranean floristic elements dominate all three surveyed areas.

Table 2. Numbers (N) and percentages (%) of members of different phytogeographic elements in the benthic floras of Kornati, Vis-Biševo and Jabuka.

#### ACKNOWLEDGEMENTS

We are indebted to Duško Dančuo, the diver of the Club for Underwater Activities "Delfin", for collecting samples of phytobenthic material. We thank the authorities of the National Park "Kornati" for granting the access to the park and making available their vessels for field studies.

## Bentoska morska flora Nacionalnog parka "Kornati" (Kornatsko otočje, srednji Jadran, Hrvatska)

Ante ŠPAN and Boris ANTOLIĆ

*Institut za oceanografiju i ribarstvo, Split, Hrvatska*

### KRATKI SADRŽAJ

U ovom se radu iznosi popis svojti bentoskih alga i morskih cvjetnica koje su do sada određene na području Nacionalnog parka "Kornati". Najveći dio svojti u ovom popisu su rezultat naših istraživanja bentoske flore tog područja, koja su obavljena između 1979. i 1989. godine.

Sabiranje fitobentoskog materijala je obavljeno s pomoću samostalnih ronilaca i drežde na brojnim postajama raspoređenih uzduž transekata položenih na čvrstim i pomicnim dñima od supralitorala do cirkalitorala (100 m). Transekti su bili položeni na obalama 18 vanjskih otoka i na nekoliko hridi, te u 4 uvale na otoku Kornat i u uvali Lojena na otoku Lavernaka. Sabiranja su obavljena i na podmorskim djelovima klifova, podmorskim pragovima, brakovima te na dubljim pomicnim i koraligenskim dñima oko otoka (Slika 1).

Ukupno je do sada određeno 352 svojti bentoskih alga i 3 vrste morskih cvjetnica (ANEX). Brojem i postotkom prevladavaju svojte iz odjeljka Rhodophyta (Bangiophyceae i Floridophyceae) s 225 svojti (186 vrsta, 32 odlike, 5 oblika i 2 stadija) ili 63.9%, a slijede ih svojte iz odjeljka Phaeophyta (Fucophyceae) s 75 svojti (55 vrsta, 2 podvrste, 11 odlike, 5 oblika i 2 stadija) ili 21.3% i odjeljka Chlorophyta (Chlorophyceae) s 52 svojte (47 vrsta, 2 odlike, 2 oblika i 1 stadij) ili 14.8% (Tablica 1).

Količnik R/P za bentosku floru Kornatskog otočja iznosi 3.0 i daje joj umjereno subtropski značaj. Vrijednosti tog količnika za uspoređivanje bentoske flore vanjskih otoka Visa i Biševa (2.2), i osobito Jabuke (1.9), daju tim florama gotovo borealan značaj (Tablica 1).

Od flornih su elemenata u istraživanoj bentoskoj flori najbolje zastupljeni atlantski elementi (A) s 123 svojte ili 34.6%, slijede ih mediteranski (M) s 96 svojti ili 27.0%, te kozmopolitski (C) i subkozmopolitski (SC) elementi s ukupno 60 svojti ili 16.9% (Tablica 2).
