du Languedoc, 34095 Montpellier, Cedex 05, France

An abnormal partially-albino embryo with atypical characteristics was removed from a pregnant female sandbar shark, *Carcharhinus plumbeus*, caught in the Gulf of Gabès in southern Tunisian, central Mediterranean. The specimen is described and atypical characteristics and albinism in shark species is reviewed.

Key words: Chondrichthyes, Carcharhinidae, *Carcharhinus plumbeus*, atypical characteristics, albinism, Gulf of Gabès, southern Tunisia, central Mediterranean

INTRODUCTION

The sandbar shark *Carcharhinus plumbeus* (NARDO, 1824) is frequently and abundantly landed in fishing sites in the Gulf of Gabès (southern Tunisia, central Mediterranean; BRADAÏ *et al.*, 2002, 2004; SAÏDI *et al.*, 2003, 2005). The species is captured throughout the year and especially targeted in spring and early summer (SAÏDI *et al.*, 2003, 2005). Data about its reproductive biology were given by CAPAPÉ (1984) and SAÏDI *et al.* (2005). Recent investigations in the area allowed us to remove a partially albino embryo with atypical characteristics from a pregnant female.

DESCRIPTION OF THE SPECIMEN

A pregnant female *C. plumbeus* was captured on a swordfish longline (hook no. 4) on a sandy substrate at a depth of 40-50 m off El Keft, 70 km south of Zarzis in southern Tunisia, on June 14, 2005 (Fig. 1). The pregnant female was 1920 mm in total length and its eviscerated mass reached 30 kg. Two of the 16 embryos carried by the mother were abnormal. Unfortunately, only one specimen was recovered, the other 15 were discarded at sea.

The embryo was a male with a total length of 320 mm and weight of 194 g (Fig. 2). It was

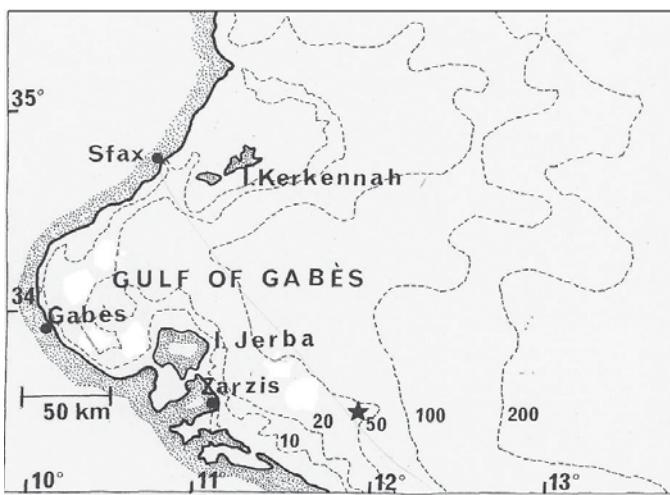

Fig. 1. Map of the Gulf of Gabès and the site of capture (★) of a pregnant female sandbar shark, *Carcharhinus plumbeus*, carrying two abnormal embryos

preserved in a 5% buffered formalin solution and deposited in the Ichthyological Collection of the Institut National des Sciences et Technologies de la Mer (INSTM), Tunisia (catalogue no. INSTM/CARCHAR 02). The main morphome-

tric measurements and counts are presented in Table 1, following COMPAGNO (1984); clasper length, following COLLENOT (1969).

The snout was conical, the distal end sharp, and the ventral surface obviously rounded (Fig. 3).

Pelvic length	30	9.4
Pelvic height	13	4.1
Anal base	17	5.3
Anal length	30	9.4
Anal height	10	3.1
Space between pectoral and pelvic fins	54	16.9
Space between vent and caudal length	160	50
Eye length	10	3.1
Eye height	6	1.9
Intergill length	15	4.7
Pre-oral length	30	9.4
Pre-orbital length	15	4.7
Space between pelvic and anal fins	30	9.4
Clasper length	30	9.4

The nasal apertures were large, oval, and lacking nasal valves. The mouth was slightly rounded. There were only four gill slits; the fifth was apparently lacking. The first dorsal fin was deformed and incomplete, with a concave upper margin. There was a large spinal curvature with a pronounced bump under the first dorsal fin. The color was grayish, with large completely unpigmented areas in the spaces between the first and second dorsal fins and both flanks. The eye is small, but not red.

DISCUSSION

During a twenty-year period, CAPAPÉ (1984, 1989) observed more than two thousand free-swimming sandbar sharks and one hundred embryos collected in Tunisian waters. Recent observations in the Gulf of Gabès (SAÏDI *et al.*, 2003, 2005) added over one thousand exemplars and two hundred embryos. Of these exemplars, only two embryos were abnormal, corroborating the view that atypical characteristics are very rare in *Carcharhinus plumbeus*, as in other shark species (HEUPEL *et al.*, 1999; BARRULL *et al.*, 2002). A literature review reveals only 33 cases of deformities in sharks (Table 2).

The snout deformity and lack of one gill slit in the present embryo may be congenital, as described by HOENIG & WALSH (1983). The large nasal apertures and lack of nasal valves may be related to the lack of the gill slit. The deformed first dorsal fin was probably the consequence of the skeletal deformity (the spinal curvature with pronounced bump).

The litter size in pregnant female sandbar sharks (1720-2185 mm TL) from the Gulf of Gabès ranges 2-12 embryos, with a positive relationship between litter size and total length (SAÏDI *et al.*, 2005). Therefore, the litter of 16 in the current female was exceptionally high and, perhaps, some embryos could not develop under optimal conditions, partially explaining the atypical characteristics of the examined specimen.

The origin of skeletal deformities generally remains uncertain. HEUPEL *et al.* (1999) attributed such deformities to parasitic infection, arthritis,

injury, tumors, malnutrition, or congenital abnormality. Of seven *Glyphis* sp. C collected from western Australian freshwater bodies, three had spinal deformations (HEUPEL *et al.*, 1999) caused by genetic abnormality, indicative of inbreeding within a small gene pool (THORNBURN & MORGAN, 2004). Skeletal deformities occur in aplacental viviparous sharks such as *Galeorhinus galeus* and *Furgaleus macki* and placental sharks such as triakids and carcharhinids that develop chambers containing single embryos during gestation, as in the case of the Tunisian specimen.

A literature review revealed only twenty cases of partial and/or full albinism in 18 shark species (Table 3). The scarcity of this phenomenon may be the result of the aberrant coloration making albinos easy prey for larger specimens (TALENT, 1973). However, some albino specimens reach a large size, such as a tawny nurse shark, *Nebrius ferrugineus*, of 2904 mm TL, recorded

off Japan by TANIUCHI & YANAGISAWA (1987) and a zebra shark, *Stegostoma varium*, 1850 mm TL, caught in the Indian Ocean. TALENT (1973) first reported albinism in embryos in a viviparous species, *Mustelus californicus*, in which the entire litter was affected. The two abnormal embryos in our study were partial albinos, and the lack of pigmentation does not seem to be congenital; it may have resulted from the large number of embryos carried by the mother. No previous cases of partial or full albinism were reported for sharks in Tunisian waters and only two cases were recorded for free-swimming batoid species (CAPAPÉ & PANTOUSTIER, 1975; BEN BRAHIM *et al.*, 1998). This record is the second record of a specimen with both deformities and albinism, the first was described by TANIUCHI & YANAGISAWA (1987).

SAŽETAK

Neuobičajeni embrio s atipičnim obilježjima, djelomično albino, koji je odstranjen iz skotne ženke psa tupana, *Carcharhinus plumbeus* uhvaćen je u Gabeškom zaljevu (južni Tunis), centralni Mediteran. U ovom radu opisan je nađeni primjerak. Dat je pregled atipičnih obilježja i albinizma ove vrste morskog psa.

Ključne riječi: Chondrichthyes, Carcharhinidae, pas tukan *Carcharhinus plumbeus*, atipična obilježja, albinizam, Gabeški zaljev, južni Tunis, centralni Mediteran
